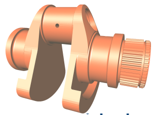
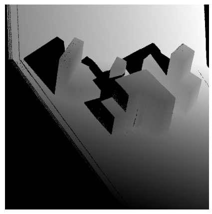
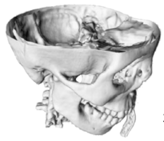
1

3D Shape Modelling

- How to obtain a mesh?
- Input data
  - Range images
  - Volumetric voxel images
  - CAD/CAM
  - Dirty meshes provided by graphic designers
  - 2D Images + stereovision



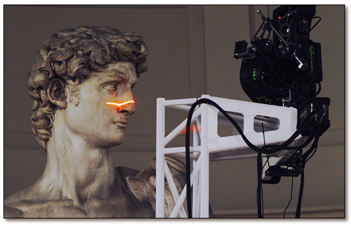




2

2

3D objects digitization

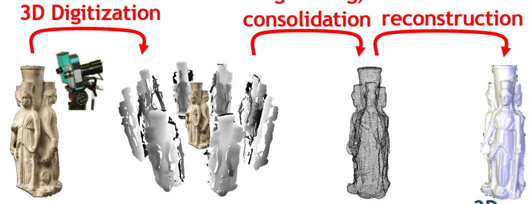


Laser scanner (Michelangelo Project)

3

3

From 3D digitization to surface reconstruction



Art3D project (ANRT)

4

4

Shape Reconstruction

- Problem of 2D reconstruction
  - Reconstruct a curve from 2D input point samples on that curve
- Problem of 3D reconstruction
  - Reconstruct a surface from 3D input point samples on that surface

5

5

Case of a digital terrain model

- Data can be parameterized as a height function with respect to a reference plane (2D ½ dimension)
- Delaunay triangulation of the points projected on the reference plane
  - Triangulation maximizing the angles of the triangles projected on the 2D plane, not the angles of the 3D triangles

6

6

Case of a digital terrain model

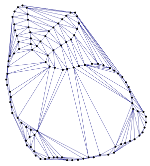
- How to better consider the height information?
  - Find the triangulation maximizing the angles of the 3D triangles
    - Remark : each pair of adjacent triangles can locally be flattened with a preservation of the angles
    - It is possible to reuse Lawson's flipping algorithm, without guaranteeing a global optimum
    - Non Delaunay edges $\Pi - (\alpha + \beta) < 0$

7

7

Mesh generation from a 2D or 3D point set

- 2D Reconstruction
  - Look for the curve as a sub-graph of the 2D Delaunay triangulation
  - Provided it should be present in it!
- 3D Reconstruction
  - Look for the surface mesh as a sub-graph of the 3D Delaunay triangulation



8

8

In the following…

- We will distinguish
  - The original shape on which the input points have been sampled and which one seeks to to approximate
  - The provided samples
- Care should be taken to maintain an equivalence between continuous and discrete notions

9

9

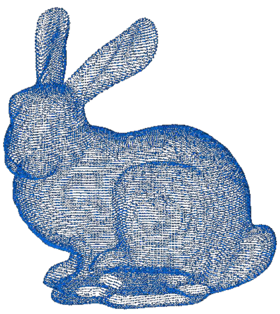
One of the first reconstruction algorithm

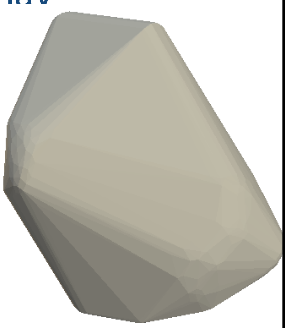
- CRUST (Amenta et al)
  - Algorithm provided with necessary and sufficient conditions on the sampling density to guarantee the result of the reconstruction
  - Minimal Sampling density characterized by using the « Local Feature Size » : distance from the surface points to the skeleton (medial axis) of the shape
  - Skeleton : set of maximal balls centers approximated by Voronoi Centers

10

10

Other algorithms based on Delaunay



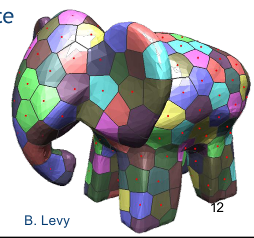


11

11

Restricted Voronoi Diagram

- Given a set of points on a surface
  - Restricted Voronoi cell :
    - Intersection between a Voronoi cell and the surface
  - Can be used to construct triangles between points with adjacent restricted Voronoi cells



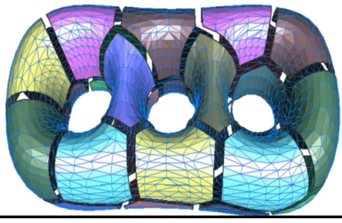
B. Levy

12

12

Voronoi diagram restricted to a surface

- Restricted Voronoi diagram
  - Intersections between the 3D Voronoi cells and the surface of the original shape (if ever we have it!!)



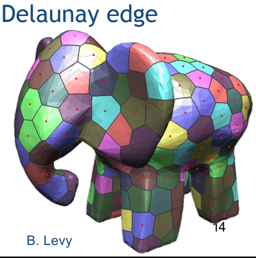
B. Levy

13

13

Restricted Delaunay Triangulation

- Restricted Delaunay :
  - Defined by duality
  - Each adjacency between 2 restricted Voronoi cells results in a restricted Delaunay edge
  - Creation of triangles of restricted Delaunay by duality to a vertex of Restricted Voronoi



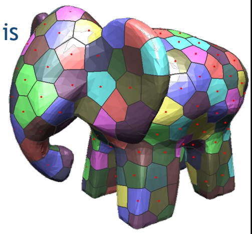
B. Levy

14

14

Restricted Delaunay Triangulation

- Edelsbrunner and Shah's theorem[1997]
  - If each face of the Restricted Voronoi diagram is **homeomorph to a topological disc,** then the restricted Delaunay triangulation is homeomorphic to the unknown surface.



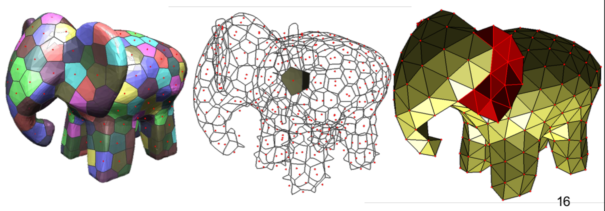
B. Levy

15

15

Restricted Delaunay Triangulation

- Topological disk property not satisfied for insufficient sampling....



B. Levy

16

16

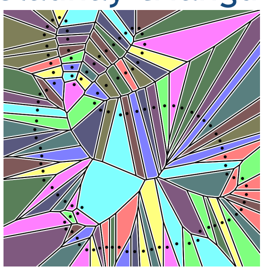
Restricted Delaunay Triangulation

- In presence of an ε-sampling with ε<0.1, the property of the topological disk is satisfied [Amenta and Bern 99]
- The problem is that we do not know the original surface, and we need it to build the restricted Voronoi cells and the associated dual triangulation...

17

17

What if the surface is unknown? Cocone : An other reconstruction approach using Voronoi diagram and Delaunay triangulation

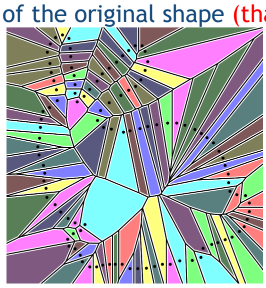


18

18

Voronoi diagram restricted to a curve

- Restricted Voronoi diagram
  - Intersections between the 2D Voronoi cells and the curve of the original shape (that we do not know !!)



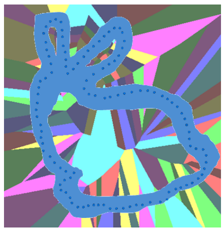
B. Levy

19

19

Cocone

- Idea: find some kind of thickened version of the original surface and make a restricted Delaunay triangulation of this thickened version



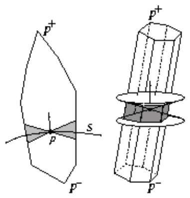
B. Levy

20

20

Cocone

- Thickening of the unknown surface :
  - For this purpose, a Cocone is placed at each sampled point [Amenta et al 2000]
  - Positioning using the tangent plane
    - using unoriented normal or estimating it from Voronoi 3D cell
  - A triangle is created from every triplet of adjacent cocones
    - Residual filtering still needed (non manifoldness)



21

21

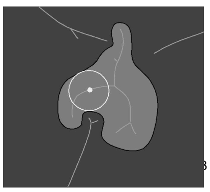
Other reconstruction approaches based on an approximation of the skeleton

22

22

Power Crust

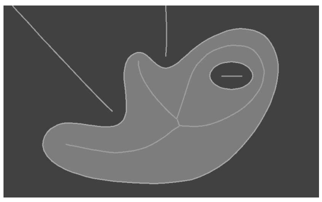
- Observation :
  - any point of a compact surface is on the boundary of two maximal balls centered on the skeleton
  - an outer ball and an inner medial ball
- Use the idea that the inside of any closed surface is a union of balls



23

Back to the medial axis/ skeleton

- In 2D :
  - Center of the maximal balls contained within the curve
  - All points that have more than one nearest neighbor on the curve

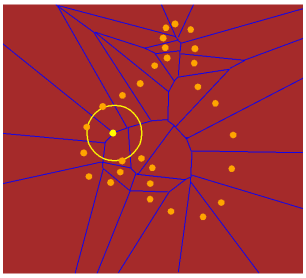


24

24

Back to the medial axis

- 2D approximation :
  - Voronoi balls are the discreet equivalent of maximal balls



25

25

2D reconstruction

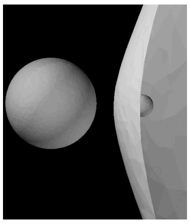
- By approximating the medial axis
  - We can therefore approximate a 2D shape as a union of inner Voronoi balls
  - What we need to know is which balls are inside (resp. outside) or at least which ones have different signs

26

26

Back to the Medial Axis

- In 3D:
  - The medial axis of a surface is a surface (possibly with pieces of curves)

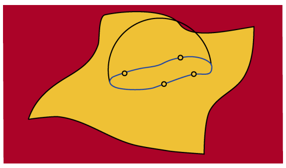


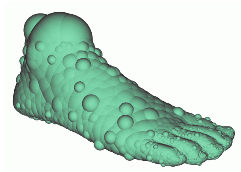
27

27

3D reconstruction by approximating the Medial Axis

- 3D approximation:
  - Beware of Voronoi balls that are centered on the surface (sliver)
  - Even for a good surface sampling

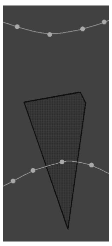




28

Back to Voronoi

- In case of a dense and noise free sampling
  - Long and thin Voronoi cells,
  - Direction aligned with the normal to the surface
  - With extremities close to the medial axis

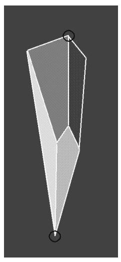


29

29

Poles

- Poles
  - Voronoi vertices at the extremities of the elongated cells

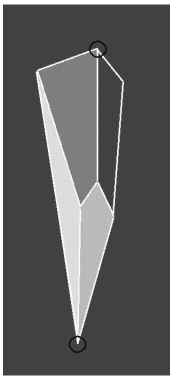


30

30

Poles

- Approximation
  - Let V_p be the Voronoi cell of a point p
  - Positive pole p^+ : Voronoï vertex of V_p furthest from p.
  - Vector pole pp^+ : approximation of the normal direction at p.
  - The negative pole p^- : vertex of V_p furthest from p^+ in the direction opposite to the vector pp^+

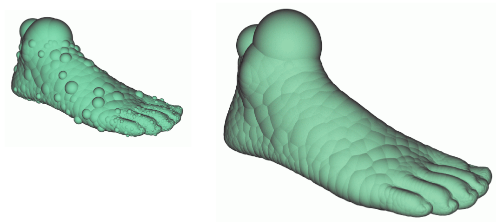


31

31

3D reconstruction by approximating the medial axis

- 3D approximation:
  - Retain only polar balls (centered on the poles)



Amenta and Bern 98

32

32

3D reconstruction by approximating the medial axis

- 3D approximation:
  - Retain only polar balls (centered on the poles)
  - Yes, but which ones?

33

33

Power Crust

- It is difficult to know which polar balls are internal
- However, local criteria make it possible to distinguish polar balls of different natures
  - Two adjacent "deeply intersecting" polar balls are considered to be on the same side of the surface
  - Two "barely intersecting" polar balls are one internal and the other external

34

34

Power Crust

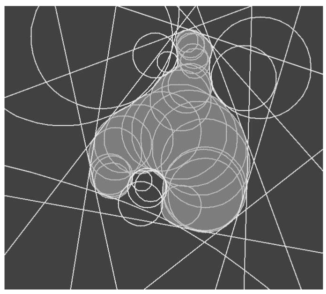
- Labelling of polar balls
- Global heuristics
  - "External" labelling of the poles incident to a large enclosing box
  - Propagation of labels:
    - For any pole p labelled "external".
      - each unlabelled neighbor q such that the polar balls associated with p and q intersect deeply is labelled "external".
      - For each point s of S considering p is the pole, the other pole is labelled internal.
    - For any pole labelled "internal".
      - Symmetrical work
  - Using a priority queue

35

35

Power Crust

- How to switch from a set of balls to a mesh?

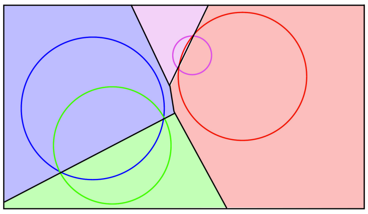


36

36

Power Crust

- How to switch from a set of balls to a mesh?
  - Construction of a ball power diagram.



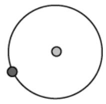
37

37

Power diagram

- Can be seen as a Voronoï diagram of balls with an adhoc metric
  - Ball B of center c and radius r
  - Power distance of a point x with respect to B :

$$d_{pow} = d^2(c,x) - r^2$$

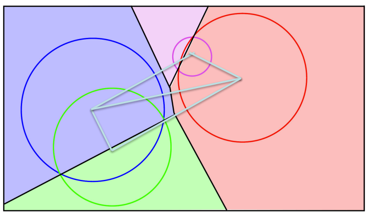


38

38

Power Crust

- Note: The dual of a power diagram is a triangulation connecting the centers of the circles (Regular triangulation)

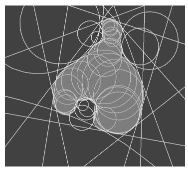


39

39

Power Crust

- Construction of a power diagram using polar balls
- Reconstructed surface:
  - set of facets of the diagram whose dual edges link an inner pole and an outer pole.



40

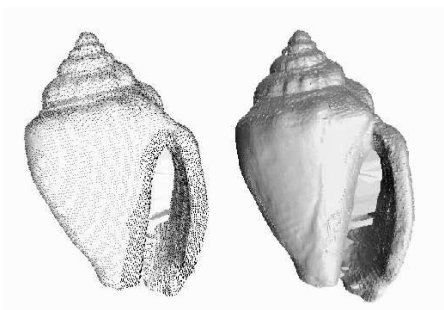
40

Power-Crust Results

41

41

Power Crust results

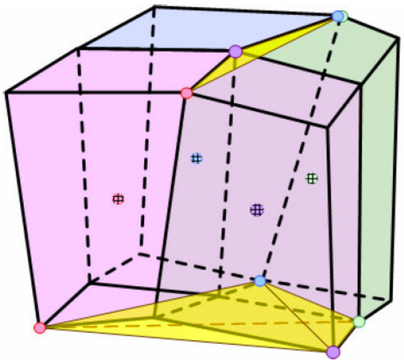


- Natural filling of the holes

42

42

Power-Crust Result



43

43

Power Crust

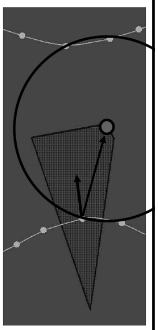
- Robustness:
  - The output mesh is the boundary of a solid (by construction) but does not only contain triangles
  - No surface extraction or hole filling steps
- Correctness:
  - Theoretical results that relate the geometric and topological validity of the result to the quality of the sampling

44

44

Power Crust

- Correctness:
  - All the (wide) polar balls passing through a sample s are nearly tangential to the surface in s

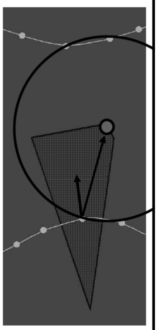


45

45

Power Crust

- Given a ε- sampling of a surface S, the angle between the normal at S in s and the vector joining s to one of its poles is in O (ε)



46

46

Power Crust Results

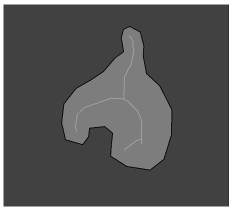
- Robustness to noise

47

47

Power Crust

- Power crust also provides an approximation of the medial axis
- Connection of the inner poles with adjacent cells in the power diagram



48

48

Power Crust results

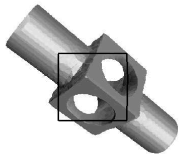
- Simplification of the skeleton (noisy samples or not)

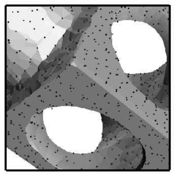
49

49

Power Crust Results

- Sharp edges can be inferred



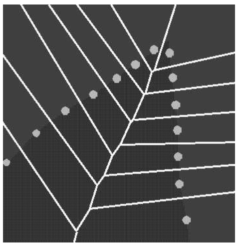


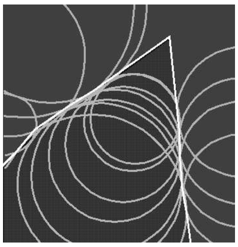
50

50

Power Crust results

- Respect of sharp edges :
  - Ignore poles associated with malformed Voronoi cells



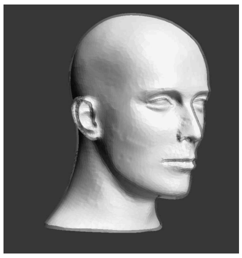


51

51

Offset surface management

- Narrowing of the internal polar balls
- Widening of the external polar balls

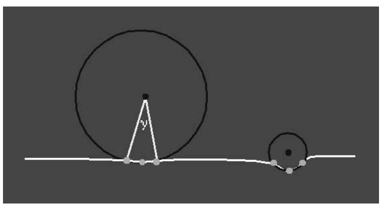


52

52

Handling noise

- By simplifying the medial axis
- Delete polar balls associated with vertices that are too close to the pole



53

53
